

# Access Node-RED Dashboard from Anywhere using Digital Ocean

This guide explains how to install Node-RED software on a Linux Ubuntu VM (Virtual Machine) using Digital Ocean. Running Node-RED in the cloud allows you to access your Node-RED Dashboard from anywhere.

You can also [install the MQTT Mosquitto Broker](#) in your VM to connect several ESP32/ESP8266 boards and other IoT devices from anywhere using different networks with an Internet connection.

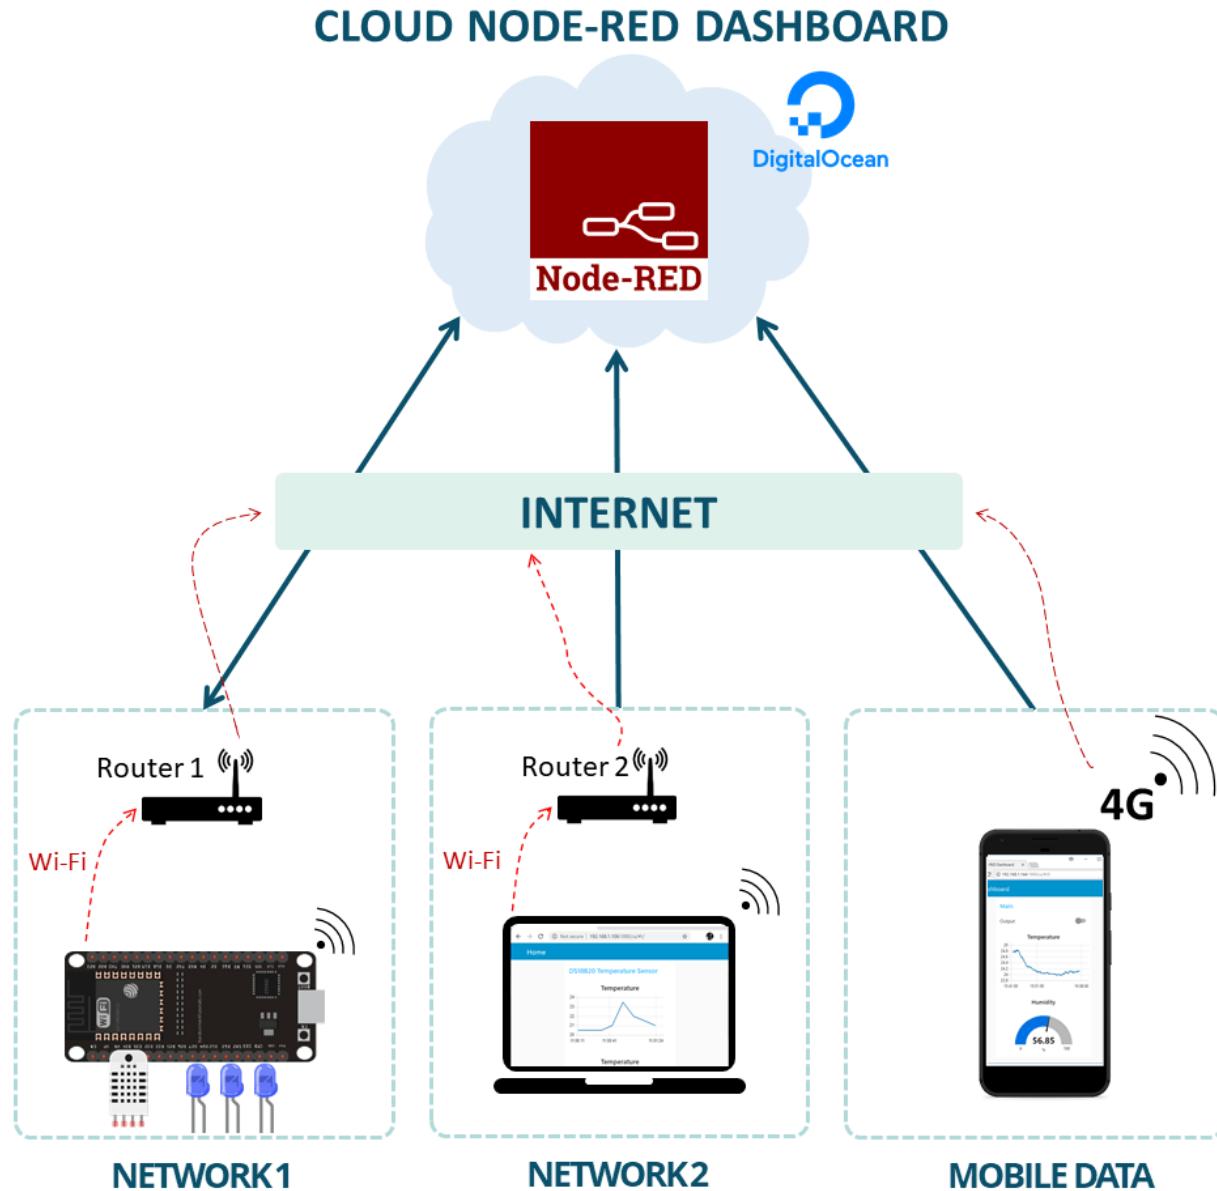

## Introducing Node-RED

Node-RED is a powerful tool for building Internet of Things (IoT) applications using visual programming: connect code blocks (nodes) together to perform a task.

Node-RED provides a dashboard ([Node-RED dashboard](#)) that can be used as an Home Automation platform to interact with IoT devices to control outputs and monitor sensors.

You can easily establish a communication with Node-RED and your ESP32/ESP8266 boards using [HTTP requests](#) or [MQTT](#), for example.

What's the advantage of installing Node-RED on the cloud (Digital Ocean hosting service) and how it works? Here's an example.

- You have Node-RED software and Node-RED dashboard installed on Digital Ocean.
- The ESP32 can communicate with Node-RED as long as it is connected to a router with access to the internet.
- The ESP32 can send sensor readings to Node-RED and/or you can control its outputs by accessing the dashboard.
- You can access Node-RED dashboard using your computer or your smartphone from anywhere in the world.

- This allows you to control and monitor one or multiple [ESP32/ESP8266](#) boards from anywhere.

## Hosting Service – Digital Ocean

To run your Cloud MQTT Mosquitto Broker, you need to use a hosting service that allows you to have access to the command line and install any software that you need. I recommend using [Digital Ocean](#) that offers an Ubuntu server that you can manage through a command line.

I've been using it since 2015 and I personally recommend it, but you can use any other hosting service. Any hosting service that offers a Linux Ubuntu VM with full console access should work.

If you don't have a hosting account, I recommend [signing up for Digital Ocean](#). When you sign up for Digital Ocean, you can try it for 60 days (they give you free credits to test the platform).

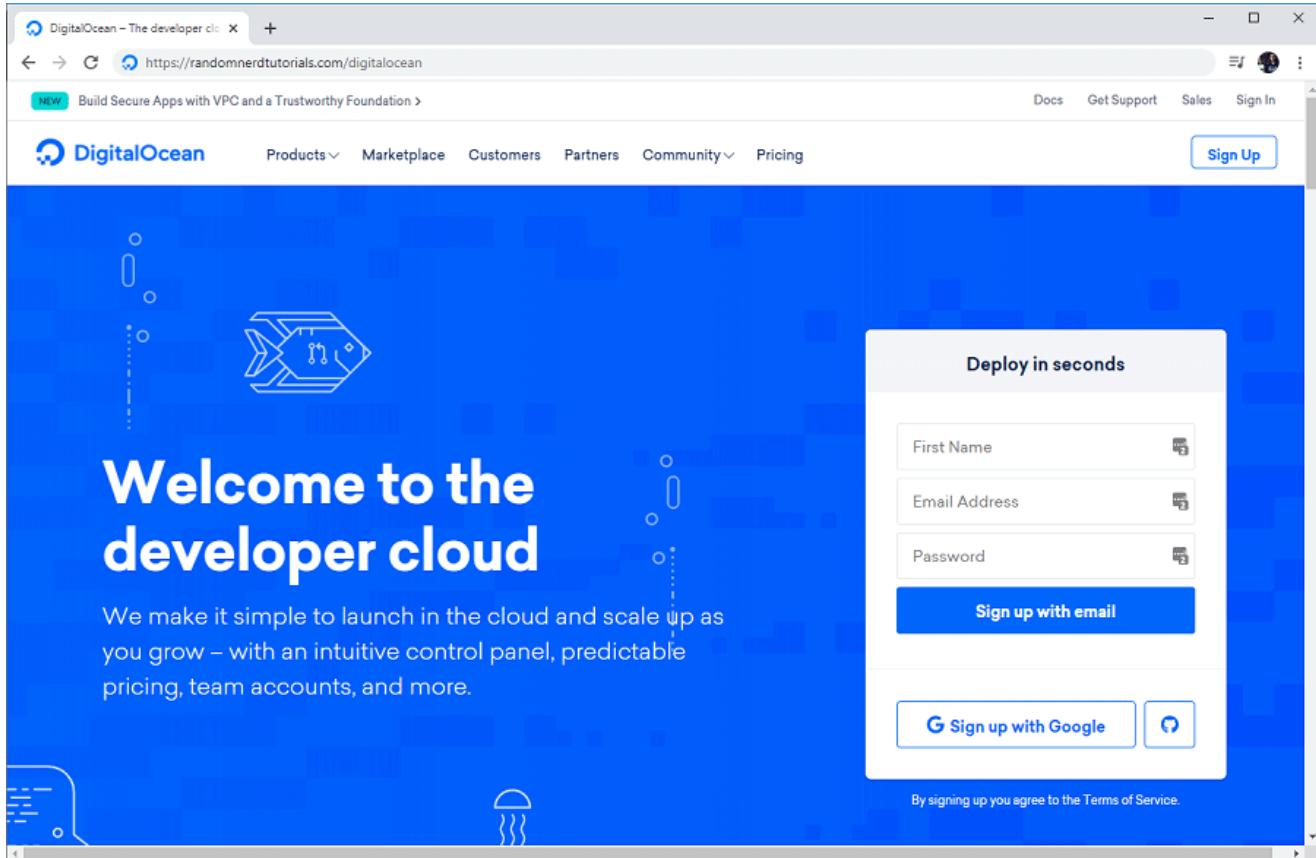

[Grab Linux Ubuntu VM on Digital Ocean »](#)

If you like our projects, you might consider signing up to the recommended hosting service, because you'll be supporting our work.

**Note:** you can also run Node-RED in your local network using a Raspberry Pi board. However, the purpose of this tutorial is to run Node-RED in the cloud to communicate with boards (or other IoT devices) across different networks.

## Creating Digital Ocean Account

To create a Digital Ocean Account, go to [Digital Ocean](#) and press the “**Sign Up**” button.

Create your account, and you'll receive a \$100 credit that you can use for 60 days to test the platform. You might need to enter a valid credit card, but you can cancel your account anytime if you're no longer interested in using the service after the free 60 days trial.

Complete the account creation using your preferred method (I always use the Email option).

Try DigitalOcean with a \$100 credit 

You will receive a \$100 credit (good for 60 days) when you create a new account on DigitalOcean

## Create your account

And start spending more time on your projects and less time managing your infrastructure.

 [Sign Up with Email](#)

 [Sign Up with Google](#)

 [Sign Up with GitHub](#)

By signing up you agree to the [Terms of Service](#) and [Privacy Policy](#)

Confirm your account and login, you should see a similar Dashboard.

The screenshot shows the DigitalOcean Cloud interface for the 'Rui Santos' project. The left sidebar includes 'PROJECTS', 'Rui Santos' (selected), '+ New Project', 'MANAGE', 'DISCOVER', and 'ACCOUNT'. The main area displays the project name 'Rui Santos' (DEFAULT), a search bar, and a 'Create' button. Below this is a 'Resources' tab, an activity feed, and a 'DROPLETS (3)' section showing three active droplets. A 'Move Resources' button is also visible.

## Create a Droplet (Linux Ubuntu VM)

To create a new VM, press the “**Create**” button on the top right corner and select the “**Droplets**” option. Digital Ocean calls **Droplets** to its VMs.

**Important:** if you’re already running a Droplet with MQTT Mosquitto Broker, you can skip these next steps (creating a Droplet). You can run both Node-RED and Mosquitto MQTT broker in the same server.

The screenshot shows the DigitalOcean dashboard interface. At the top, there's a search bar and a green 'Create' button with a dropdown arrow. To the right of the 'Create' button are icons for a gear and a bell. A red box highlights the 'Droplets' section, which contains the text 'Create cloud servers' and an icon of a blue water droplet. Below this, there are sections for 'Clusters', 'Databases', 'Volumes', 'Domains/DNS', 'Cloud Firewalls', and 'Floating IPs', each with their respective icons and descriptions. On the left side of the main content area, there's a user profile for 'Rui Santos' with a 'DEFAULT' status, and a 'Resources' tab is selected. In the center, there's a list titled 'DROPLETS (3)' showing three items, each represented by a green dot and a blue water droplet icon. At the bottom of the main content area, there's a 'Resources' tab, an 'Activity' tab, and a 'Settings' tab.

For this guide I'll be using Ubuntu 20.04 (LTS) x64, and I recommend choosing the same option. You can also use the “**Basic**” starter plan.

The screenshot shows the 'Create Droplets' page. At the top, there's a search bar and a green 'Create' button with a dropdown arrow. To the right of the 'Create' button are icons for a gear and a bell. Below the 'Create' button, the title 'Create Droplets' is displayed. Underneath the title, there's a 'Choose an image' section with a question mark icon. Below this, there are tabs for 'Distributions', 'Container distributions', 'Marketplace', 'Snapshots', 'Backups', and 'Custom images', with 'Distributions' being the active tab. A red box highlights the 'Ubuntu' distribution card, which features the Lubuntu logo and the text 'Ubuntu'. Below the distribution name, there's a dropdown menu showing '20.04 (LTS) x64'. To the right of the Ubuntu card are cards for 'FreeBSD', 'Fedora', 'Debian', and 'CentOS', each with their respective logos and dropdown menus for selecting a version. Below the distribution selection, there's a 'Choose a plan' section. It shows two main categories: 'STARTER' and 'PERFORMANCE'. Under 'STARTER', the 'Basic' plan is highlighted with a red box. Under 'PERFORMANCE', there are options for 'General Purpose', 'CPU-Optimized', and 'Memory-Optimized'. A 'Help me choose' link is located at the top right of the 'Choose a plan' section. At the very bottom of the page, there's a footer with a link to the website and a page number '6/29'.

In the VM resources menu, you can choose the cheapest plan for \$5/month. Even with the lowest plan, it will run the MQTT Broker and Node-RED smoothly .

Standard virtual machines with a mix of memory and compute resources. Best for small projects that can handle variable levels of CPU performance, like blogs, web apps and dev/test environments.

<b>\$5/mo</b> \$0.007/hour	<b>\$10/mo</b> \$0.015/hour	<b>\$15/mo</b> \$0.022/hour	<b>\$15/mo</b> \$0.022/hour	<b>\$15/mo</b> \$0.022/hour	<b>\$20/mo</b> \$0.030/hour
1 GB / 1 CPU 25 GB SSD disk 1000 GB transfer	2 GB / 1 CPU 50 GB SSD disk 2 TB transfer	1 GB / 3 CPUs 60 GB SSD disk 3 TB transfer	2 GB / 2 CPUs 60 GB SSD disk 3 TB transfer	3 GB / 1 CPU 60 GB SSD disk 3 TB transfer	4 GB / 2 CPUs 80 GB SSD disk 4 TB transfer

● • •

[Show all plans](#)

Choose the Virtual Machine datacenter location closer to you, in my case I've used “London” region.

#### Choose a datacenter region

 New York	 San Francisco	 Amsterdam	 Singapore	 London	 Frankfurt
1    2    3	1    2    3	2    3	1	1	1
 Toronto	 Bangalore				
1	1				

#### VPC Network

No VPC  
 This Droplet will have no Private IP
 

▼

This resource can communicate over Private IP address only with other resources in the same VPC network. [Learn more](#)

Create the root password that allows you to access your Droplet (save this password, because you'll need it to access your server).

## Authentication

**SSH keys**  
A more secure authentication method

**Password**  
Create a root password to access Droplet (less secure)

---

**Create root password \***

**PASSWORD REQUIREMENTS**

- At least 8 characters long
- Must contain 1 uppercase (first and last characters don't count)
- Must contain 1 number
- Cannot end in a number or special character

Finally, choose a **hostname** to easily identify which Virtual Machine you are working with. I've named my Droplet as "mqtt-cloud-server". That's it, you just need to press the big green button "Create Droplet" to finish the process.

### Finalize and create

#### How many Droplets?

Deploy multiple Droplets with the same configuration.

#### Add tags

Use tags to organize and relate resources. Tags may contain letters, numbers, colons, dashes, and underscores.

Type tags here

#### Choose a hostname

Give your Droplets an identifying name you will remember them by. Your Droplet name can only contain alphanumeric characters, dashes, and periods.

— 1 Droplet +

mqtt-cloud-server

#### Select Project

Assign Droplets to a project

Rui Santos

#### Add backups

Enable backups

**RECOMMENDED**

A [system-level backup](#) is taken once a week, and each backup is retained for 4 weeks.

\$1.00/mo (per Droplet)

20% of the Droplet price

**Create Droplet**

Wait a few minutes and when the progress bar ends, your Droplet is ready.

# Accessing Your Linux Ubuntu VM Console

When your Droplet is prepared, open your newly created server (in my case, it's called "mqtt-cloud-server").

The screenshot shows the DigitalOcean interface. On the left, there's a sidebar with 'PROJECTS' and 'MANAGE' sections. Under 'PROJECTS', 'Rui Santos' is selected. Under 'MANAGE', 'Droplets' is selected. The main area shows a list of 'DROPLETS (4)'. The first item, 'mqtt-cloud-server' with IP 178.62.83.231, is highlighted with a red box.

Select the “Access” menu and press the “Launch Console” button.

The screenshot shows the DigitalOcean interface for the 'mqtt-cloud-server' droplet. The left sidebar shows 'PROJECTS' and 'MANAGE' sections. The 'Droplets' section is selected. The main area displays the droplet details: 'mqtt-cloud-server' (Ubuntu 20.04), 'ON' toggle, and network info (ipv4: 178.62.83.231). Below this, under 'Access', there's a 'Console access' section with a 'Launch Console' button, which is highlighted with a red box.

A new browser window opens up in your computer.

DigitalOcean Droplet Console - Google Chrome  
 cloud.digitalocean.com/droplets/ [REDACTED] /console?no\_layout=true

```
Ubuntu 20.04 LTS mqtt-cloud-server tty1
mqtt-cloud-server login: _
```

PUBLIC IP ADDRESS	GATEWAY:	NETMASK:
178.62.83.231	178.62.64.1	255.255.192.0

Connected (encrypted) to: QEMU (Droplet- [REDACTED])  
 If you see a black screen just click on it and press any key to activate the console window

Type your login (root) and the password defined earlier, press Enter key to access your server.

DigitalOcean Droplet Console - Google Chrome  
 cloud.digitalocean.com/droplets/ [REDACTED] /console?no\_layout=true

```
mqtt-cloud-server login: root

Connected (encrypted) to: QEMU (Droplet- [REDACTED])  
 If you see a black screen just click on it and press any key to activate the console window

There's an ***optional*** step, but it goes beyond the scope of this tutorial. It's ***not*** required to make this project work: prepare your server with non-root, sudo-enabled user and basic firewall with this [Initial Server Setup with Ubuntu 20.04](#).

## Installing Node-RED

Let's install Node-RED software.

Before installing the software, update and upgrade your server (this will take a few minutes to complete).

```
sudo apt update && sudo apt upgrade -y
```

To install Node-RED, you'll need npm:

```
sudo apt install npm -y
```

This next command installs Node-RED as a global module along with all its dependencies.

```
sudo npm install -g --unsafe-perm node-red
```

When the installation process is completed, you should see a similar message:

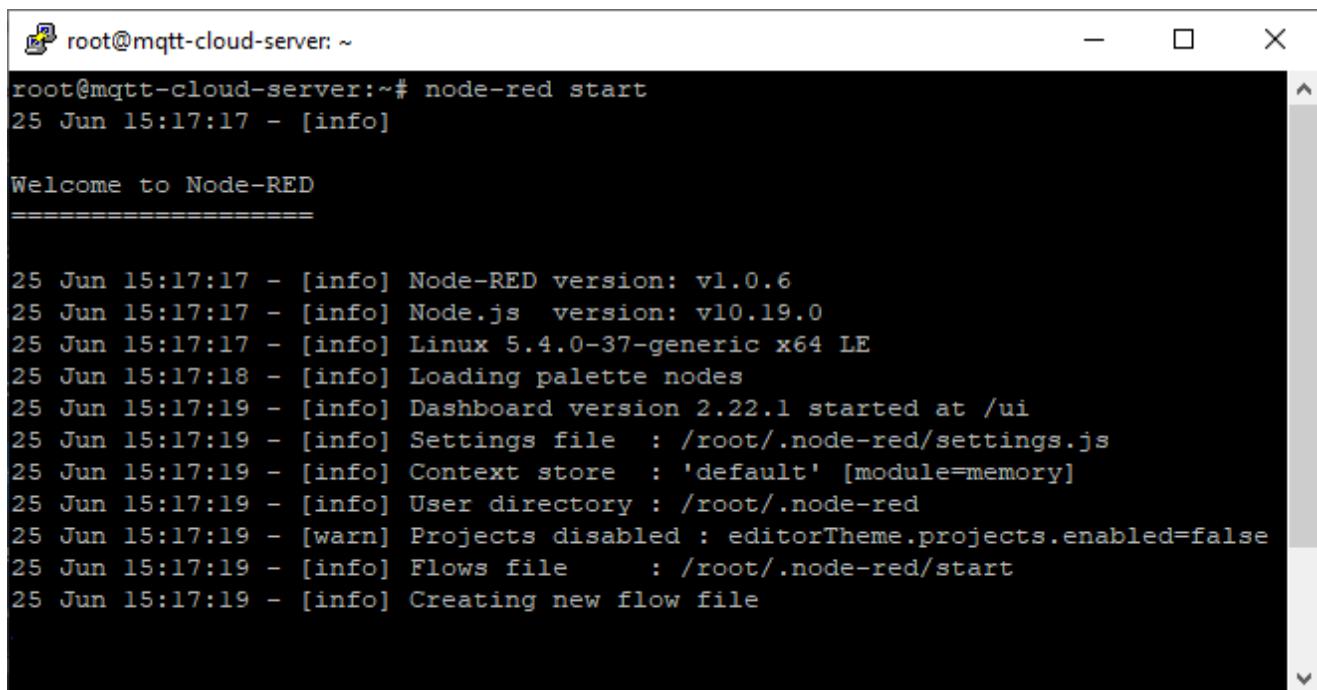

A screenshot of a terminal window titled "root@mqtt-cloud-server: ~". The window displays the command "sudo npm install -g --unsafe-perm node-red" being run. The output shows several warning messages about deprecated packages like bcrypt and request, followed by the successful installation of node-red and its dependencies. The terminal window has a dark theme with white text and a black background.

Open up a port on your server firewall. Node-RED defaults to using port 1880, so run this next command:

```
sudo ufw allow 1880
```

You can confirm it has succeeded if the end of the command output looks similar to:

```
node-red start
```

A screenshot of a terminal window titled "root@mqtt-cloud-server: ~". The window shows the command "node-red start" being run and its output. The output includes a welcome message, system information, and a detailed log of the Node-RED startup process. The log shows the version of Node-RED (v1.0.6), Node.js (v10.19.0), and the operating system (Linux 5.4.0-37-generic x64 LE). It also shows the loading of palette nodes, the start of the dashboard, settings file loading, context store configuration, user directory, and the creation of a new flow file. A warning message indicates that projects are disabled due to editorTheme.projects.enabled=false.

```
root@mqtt-cloud-server:~# node-red start
25 Jun 15:17:17 - [info]

Welcome to Node-RED
=====

25 Jun 15:17:17 - [info] Node-RED version: v1.0.6
25 Jun 15:17:17 - [info] Node.js version: v10.19.0
25 Jun 15:17:17 - [info] Linux 5.4.0-37-generic x64 LE
25 Jun 15:17:18 - [info] Loading palette nodes
25 Jun 15:17:19 - [info] Dashboard version 2.22.1 started at /ui
25 Jun 15:17:19 - [info] Settings file : /root/.node-red/settings.js
25 Jun 15:17:19 - [info] Context store : 'default' [module=memory]
25 Jun 15:17:19 - [info] User directory : /root/.node-red
25 Jun 15:17:19 - [warn] Projects disabled : editorTheme.projects.enabled=false
25 Jun 15:17:19 - [info] Flows file : /root/.node-red/start
25 Jun 15:17:19 - [info] Creating new flow file
```

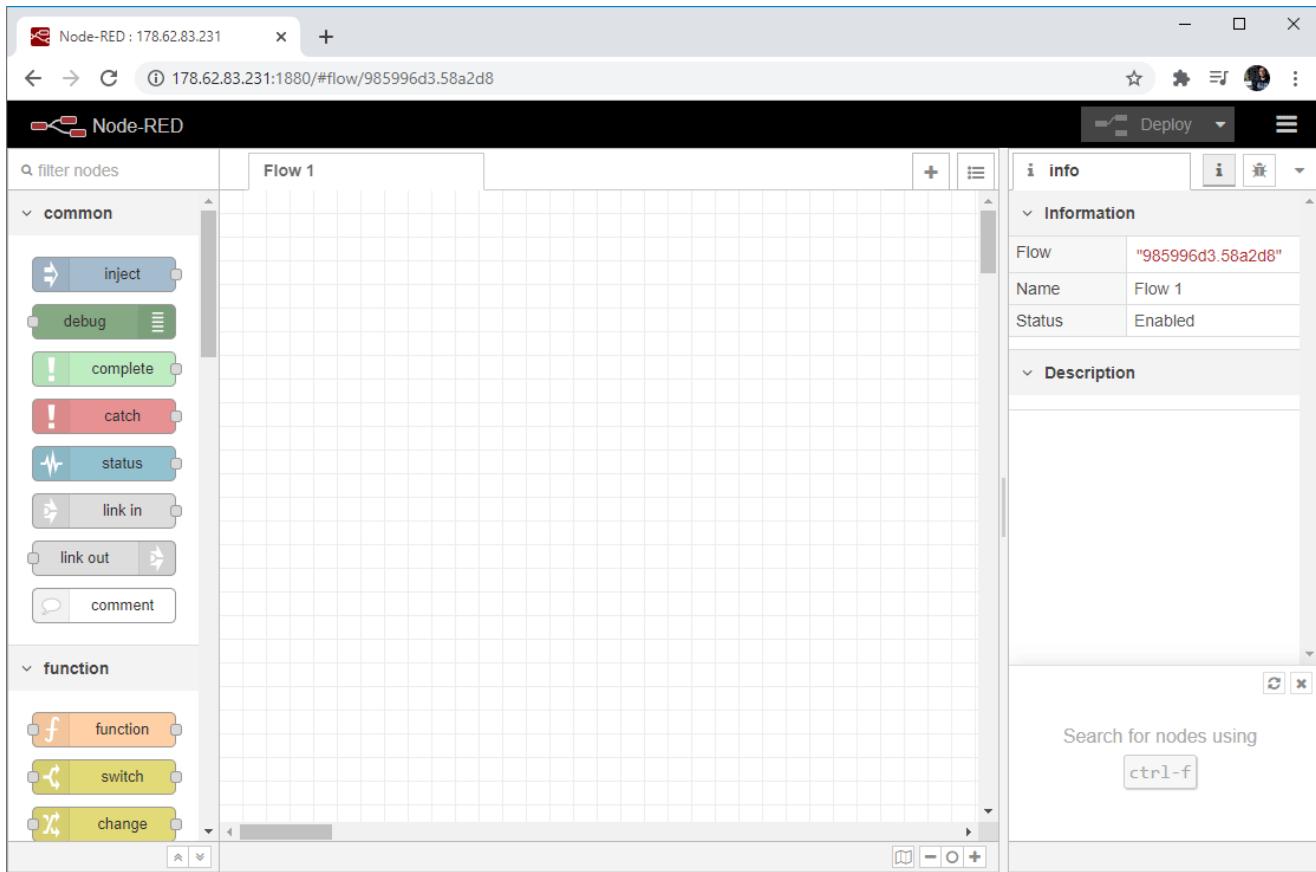

Wait a few seconds while everything loads, if you go to your Digital Ocean Droplet IP address followed by the port number 1880:

```
http://YOUR-Digital-Ocean-IP-Address:1880
```

For example:

```
http://178.62.83.231:1880
```

Node-RED software should load, here's how it should look like:

In your console window, press the **Ctrl+C** key to stop Node-RED.

## Autostart Node-RED on Boot

To make Node-RED autostart when you boot or restart your Virtual Machine, you need to create a new `systemd` file for the `nodered.service`:

```
sudo nano /etc/systemd/system/nodered.service
```

Then, add the following (if you're using root, you can leave the file as it is – otherwise comment the root and configure the non-root user option):

```
[Unit]
Description=Node-RED
After=syslog.target network.target

[Service]
ExecStart=/usr/local/bin/node-red --max-old-space-size=128 -v
Restart=on-failure
KillSignal=SIGINT

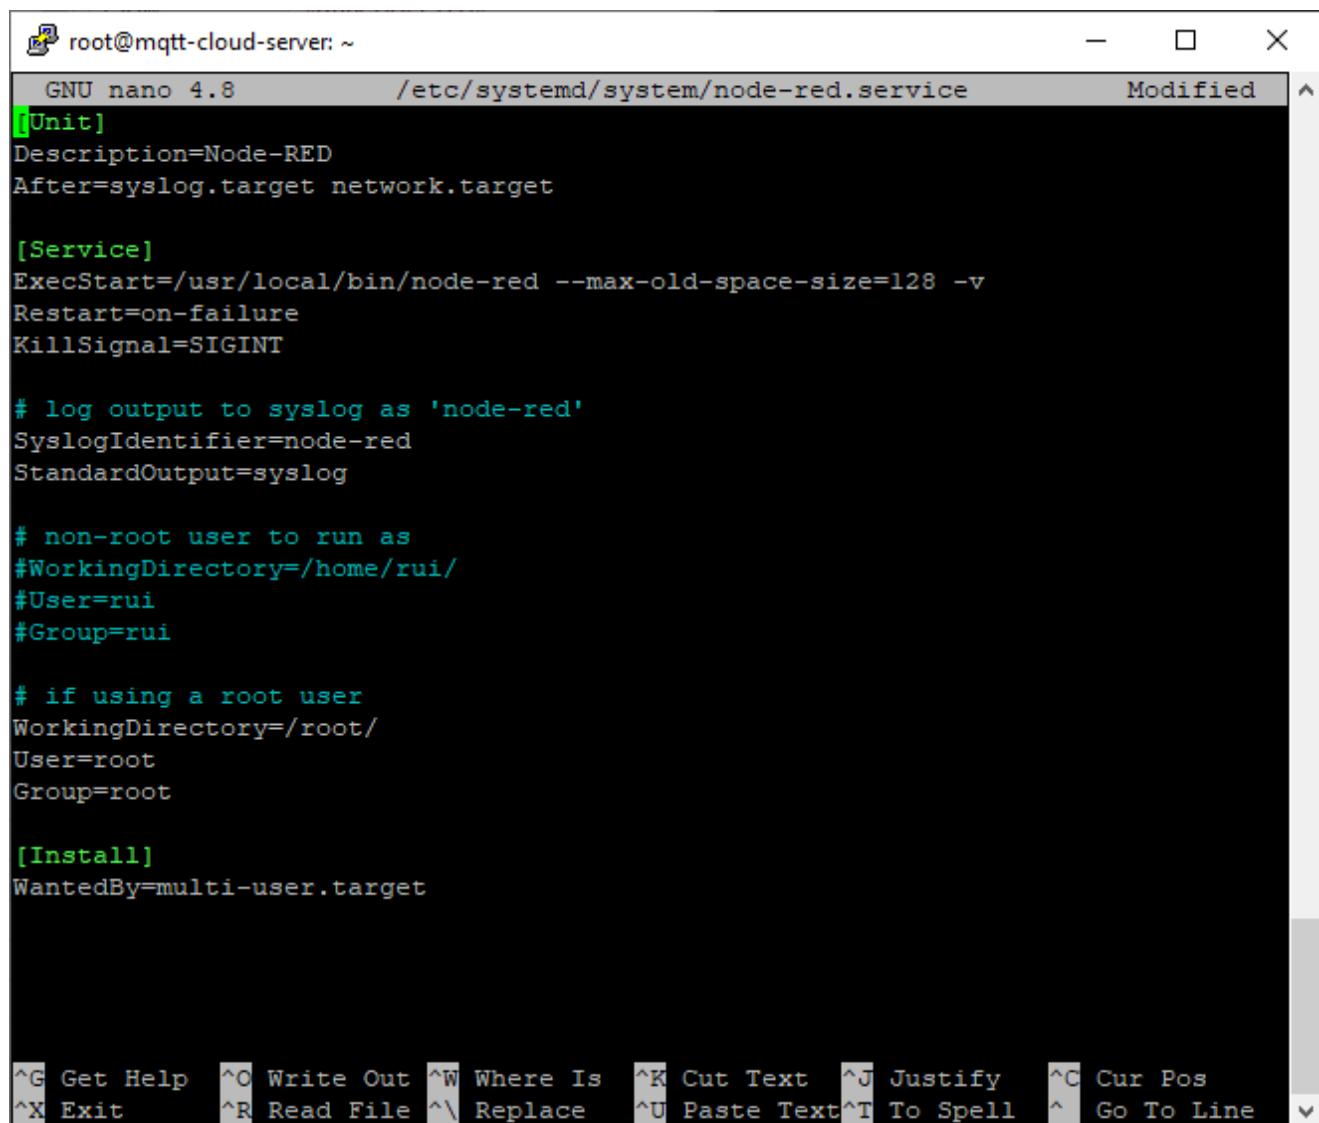

# log output to syslog as 'node-red'
SyslogIdentifier=node-red
StandardOutput=syslog
```

```
# non-root user to run as
#WorkingDirectory=/home/rui/
#User=rui
#Group=rui

# if using a root user
WorkingDirectory=/root/
User=root
Group=root

[Install]
WantedBy=multi-user.target
```

Your file should look like this, save it and exit (Ctrl+X, Y, Enter key).

```
root@mqtt-cloud-server: ~
GNU nano 4.8          /etc/systemd/system/node-red.service      Modified
[Unit]
Description=Node-RED
After=syslog.target network.target

[Service]
ExecStart=/usr/local/bin/node-red --max-old-space-size=128 -v
Restart=on-failure
KillSignal=SIGINT

# log output to syslog as 'node-red'
SyslogIdentifier=node-red
StandardOutput=syslog

# non-root user to run as
#WorkingDirectory=/home/rui/
#User=rui
#Group=rui

# if using a root user
WorkingDirectory=/root/
User=root
Group=root

[Install]
WantedBy=multi-user.target
```

To enable the Node-RED service and run this file on boot, enter the command:

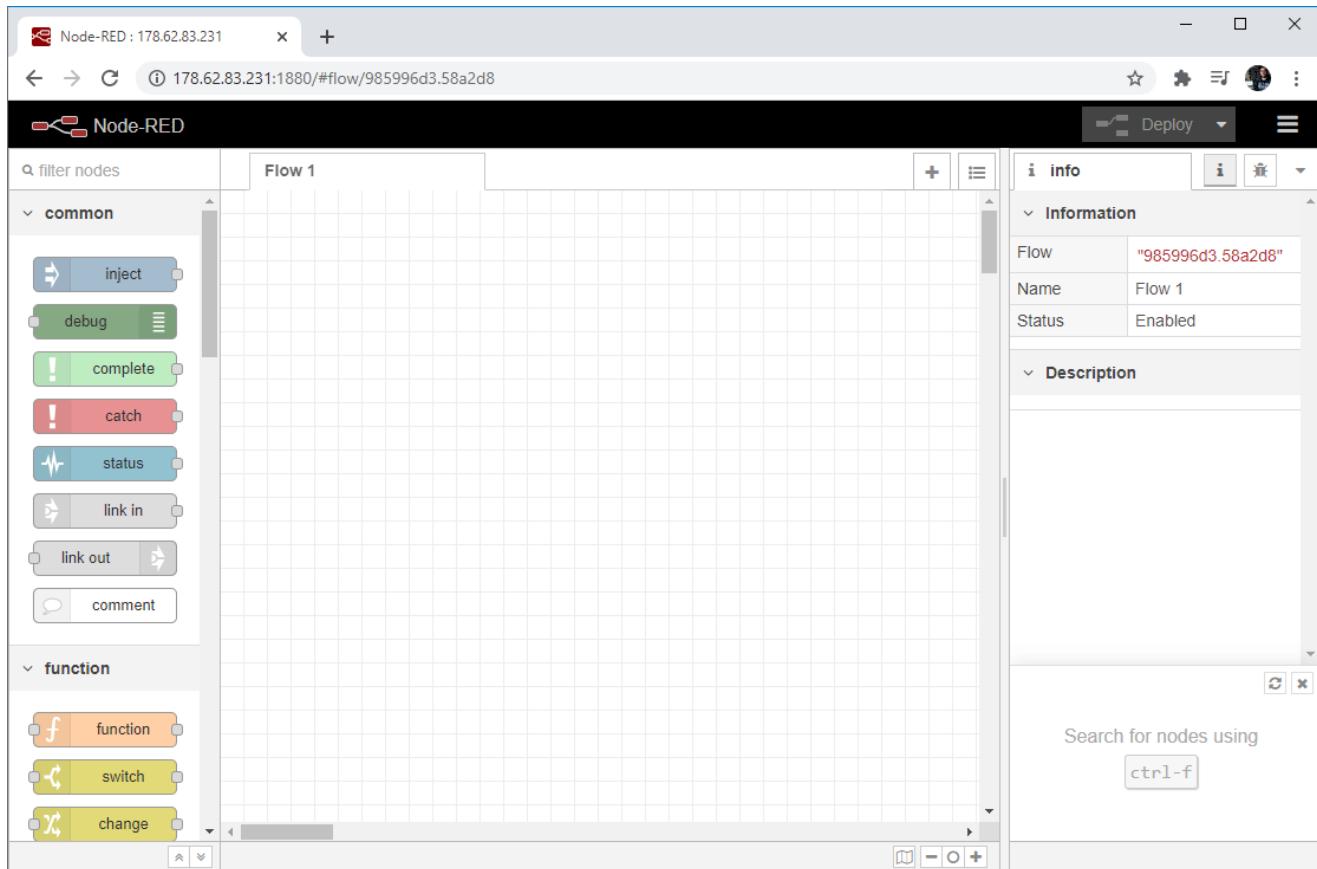

```
sudo systemctl enable nodered.service
```

Restart your Virtual Machine to test if Node-RED is automatically starting on boot:

```
sudo reboot
```

Wait approximately 2 to 3 minutes for your server to fully restart, when you open your server IP address Node-RED software should load automatically:

```
http://YOUR-Digital-Ocean-IP-Address:1880
```

That's it! Your Node-RED software is prepared.

## Securing Node-RED Software with Username and Password

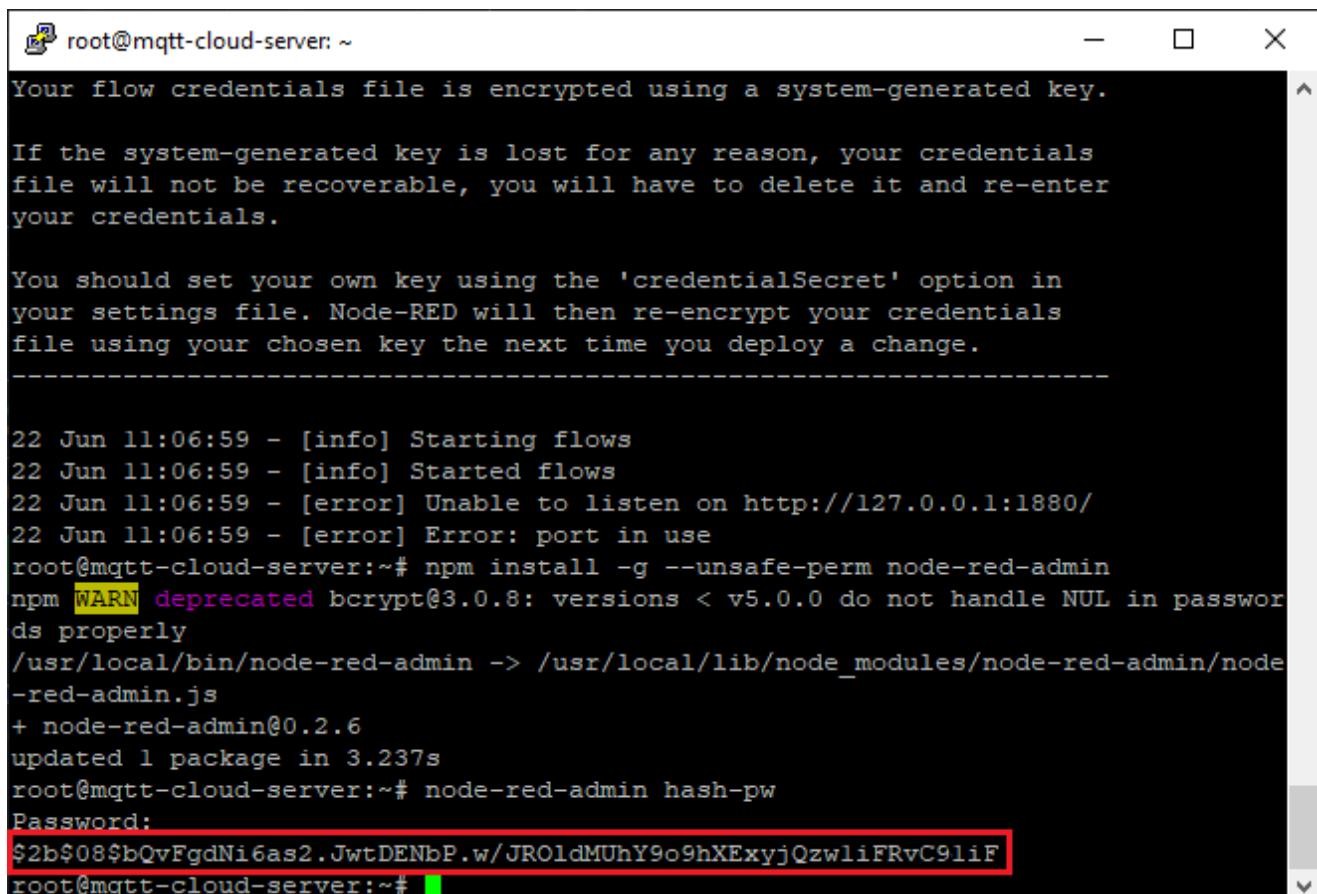

Install node-red-admin package to make it available globally:

```
npm install -g --unsafe-perm node-red-admin
```

Run the next command to create a password hash:

```
node-red-admin hash-pw
```

You will be prompted for a password. Type your desired password, press Enter key, and a hash will be printed on screen.

The screenshot shows a terminal window titled 'root@mqtt-cloud-server: ~'. It displays the following text:

```
Your flow credentials file is encrypted using a system-generated key.

If the system-generated key is lost for any reason, your credentials
file will not be recoverable, you will have to delete it and re-enter
your credentials.

You should set your own key using the 'credentialSecret' option in
your settings file. Node-RED will then re-encrypt your credentials
file using your chosen key the next time you deploy a change.

-----
22 Jun 11:06:59 - [info] Starting flows
22 Jun 11:06:59 - [info] Started flows
22 Jun 11:06:59 - [error] Unable to listen on http://127.0.0.1:1880/
22 Jun 11:06:59 - [error] Error: port in use
root@mqtt-cloud-server:~# npm install -g --unsafe-perm node-red-admin
npm WARN deprecated bcrypt@3.0.8: versions < v5.0.0 do not handle NUL in passwor
ds properly
/usr/local/bin/node-red-admin -> /usr/local/lib/node_modules/node-red-admin/node
-red-admin.js
+ node-red-admin@0.2.6
updated 1 package in 3.237s
root@mqtt-cloud-server:~# node-red-admin hash-pw
Password:
$2b$08$bQvFgdNi6as2.JwtDENbP.w/JR0ldMUhY9o9hXExyjQzwliFRvC9liF
root@mqtt-cloud-server:~#
```

Copy the hash string to your clipboard and open the Node-RED settings file. In my case the hash is:

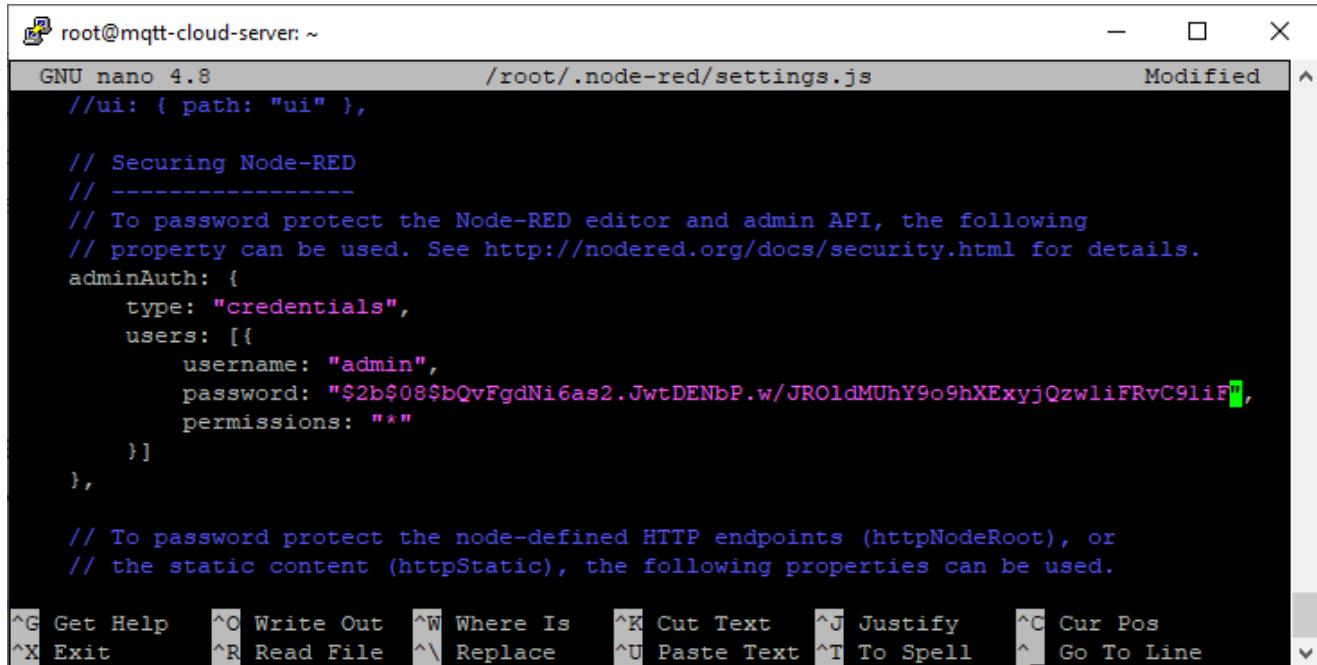

```
$2b$08$bQvFgdNi6as2.JwtDENbP.w/JR0ldMUhY9o9hXExyjQzwliFRvC9liF
```

Open the *settings.js* file:

```
sudo nano ~/.node-red/settings.js
```

Scroll down and uncomment the adminAuth block (by removing the “// ” in front of each line). Change username to whatever you like, and paste the previously

generated hash into the password field.

```
root@mqtt-cloud-server: ~
GNU nano 4.8          /root/.node-red/settings.js      Modified
//ui: { path: "ui" },

// Securing Node-RED
// -----
// To password protect the Node-RED editor and admin API, the following
// property can be used. See http://nodered.org/docs/security.html for details.
adminAuth: {
  type: "credentials",
  users: [
    {
      username: "admin",
      password: "$2b$08$bQvFgdNi6as2.JwtDENbP.w/JROldMUhY9o9hXExyjQzwliFRvC9liF",
      permissions: "*"
    }
  ],
  // To password protect the node-defined HTTP endpoints (httpNodeRoot), or
  // the static content (httpStatic), the following properties can be used.
}

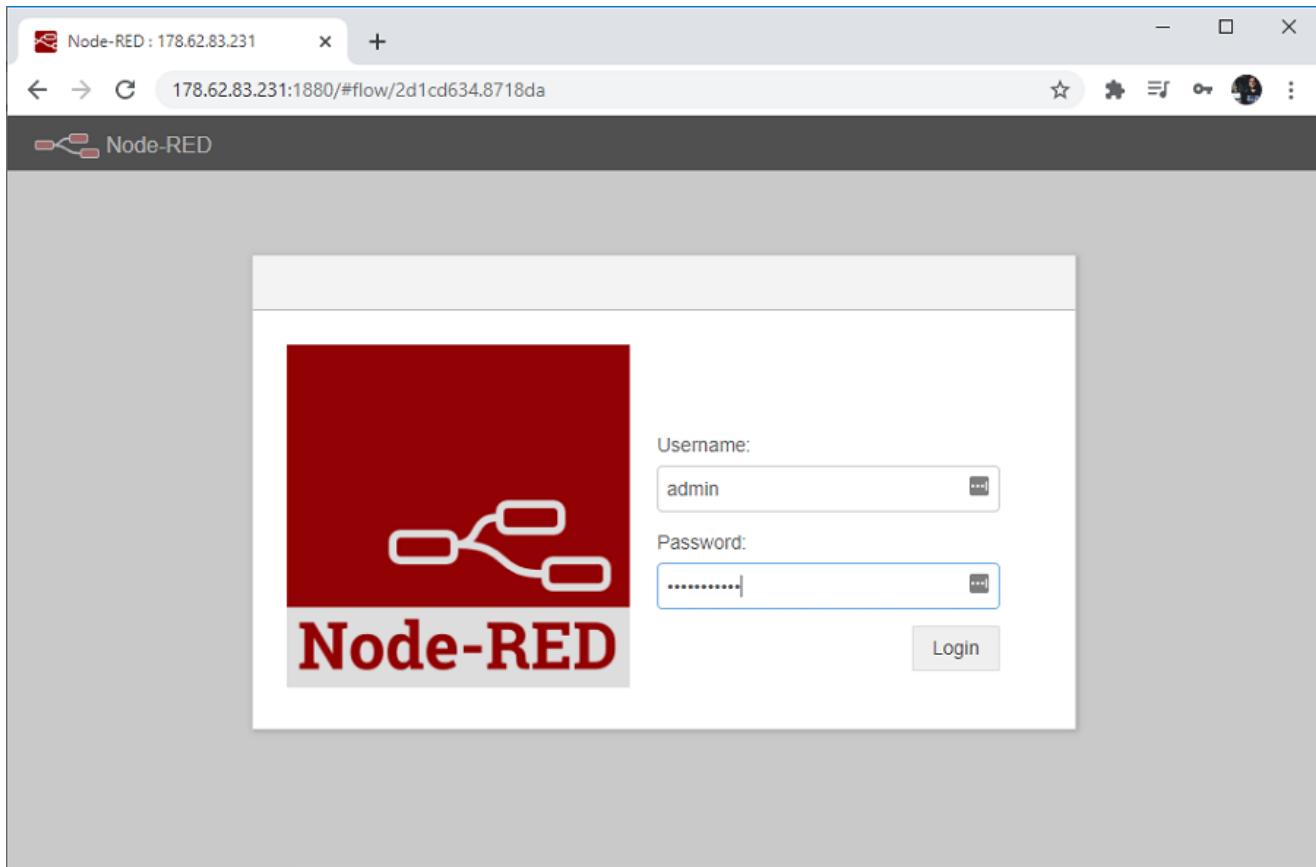

^G Get Help  ^O Write Out  ^W Where Is  ^K Cut Text  ^J Justify  ^C Cur Pos
^X Exit      ^R Read File  ^\ Replace   ^U Paste Text ^T To Spell  ^
^              Go To Line
```

Make sure you uncomment and replace the password field with the hash exactly as illustrated above, failing to do it will make it impossible to login and you'll have to repeat this process.

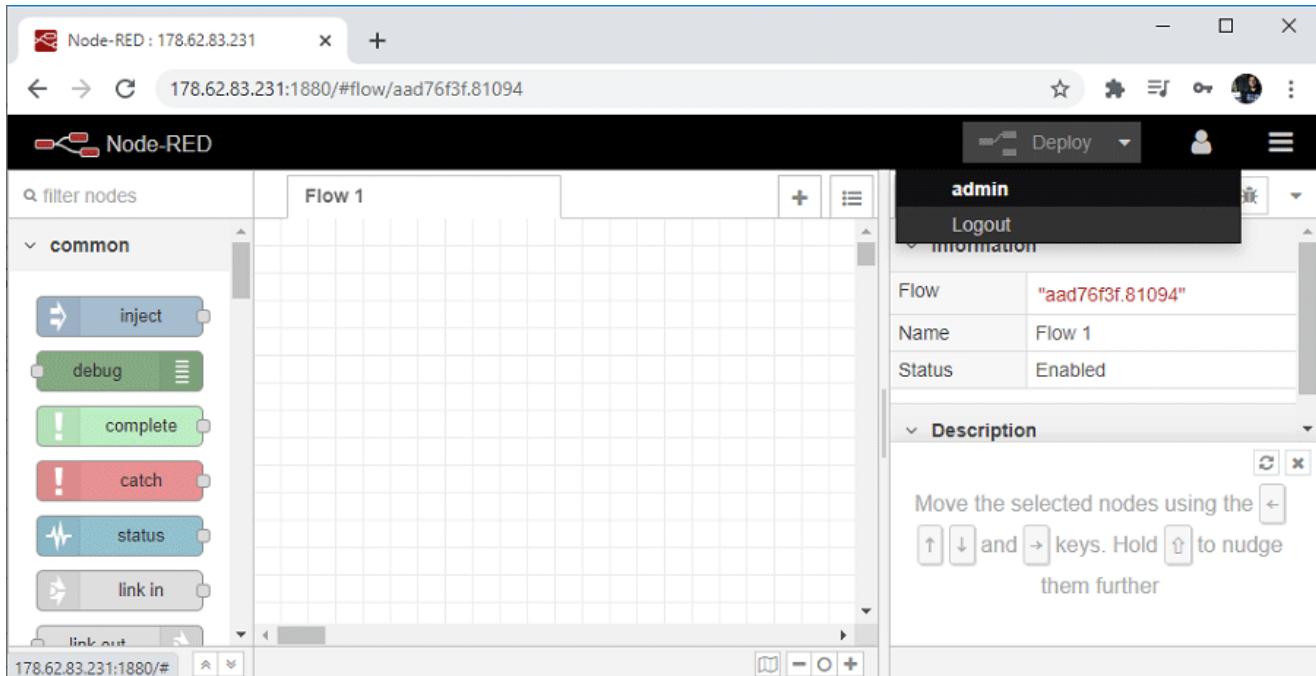

Exit the file and save it (Ctr+X, Y, Enter key). Restart your server to ensure that all changes take effect:

```
sudo reboot
```

Now, when you access your Node-RED software you'll be prompted to enter the username (default is admin) and the password defined earlier.

After logging in, you'll be redirected to Node-RED software where you can create and edit your flows. You also have a menu at the top right corner to logout.

That's it! Your server is ready and you can install Node-RED Dashboard or connect Node-RED to your [cloud MQTT broker](#).

# (Optional) Taking It Further – Node-RED SSL Certificate

The best method to add an SSL certificate to your server is by having a domain name pointed at your server and use Let's Encrypt SSL certificates.

- You'll have to buy a domain name and point it to Digital Ocean Name Servers (like example.com).
- The web server Nginx installed, with the firewall updated to allow traffic on ports 80 and 443, as described in [How To Install Nginx on Ubuntu](#) (that guide also works for version 20.04)
- Let's Encrypt installed, and a certificate generated for the domain name (like example.com). [How To Secure Nginx with Let's Encrypt on Ubuntu 20.04](#). You can ignore steps 3-5 regarding Nginx configuration, as we'll cover that next.

Having those prerequisites completed, open a new Nginx configuration for the site (replace the path with your domain name).

```
sudo nano /etc/nginx/sites-enabled/example.com
```

Copy and paste the following to the new file. You need to change the domain name and certificate paths:

```
server {  
    listen 80;  
    listen 443 ssl http2;  
    server_name example.com;  
    ssl_certificate /etc/letsencrypt/live/example.com/fullchain.pem;  
    ssl_certificate_key /etc/letsencrypt/live/example.com/privkey.pem;  
    ssl_protocols TLSv1 TLSv1.1 TLSv1.2;  
    ssl_ciphers  
        ECDH+AES128:RSA+AES128:ECDH+AES256:RSA+AES256:ECDH+3DES:RSA+3DES:!MD5;  
    ssl_prefer_server_ciphers On;  
    ssl_session_cache shared:SSL:128m;  
    ssl_stapling on;  
    ssl_stapling_verify on;  
    resolver 8.8.8.8;  
  
    location / {  
        if ($scheme = http) {  
            return 301 https://$server_name$request_uri;  
        }  
    }  
}
```

```
proxy_pass http://localhost:1880;
proxy_set_header Host $host;
proxy_set_header X-Real-IP $remote_addr;
proxy_http_version 1.1;
proxy_set_header Upgrade $http_upgrade;
proxy_set_header Connection "upgrade";
}

location '/.well-known/acme-challenge' {
    root /var/www/html;
}
}
```

Change the example.com text to your own domain name:

```
server_name example.com;
ssl_certificate /etc/letsencrypt/live/example.com/fullchain.pem;
ssl_certificate_key /etc/letsencrypt/live/example.com/privkey.pem;
```

When you're done editing the file, save it and exit the editor (Ctrl+X, Y, Enter key). Reload Nginx to pick up the new configuration.

```
sudo systemctl reload nginx
```

Finally, restart your server:

```
sudo reboot
```

Wait a couple of minutes to restart. Finally, navigate to your server:

<http://example.com>. You should be redirected to <https://example.com> (note the https) and see the Node-RED software login page. This means we're now proxying Node-RED through Nginx.

## Wrapping Up

This complete guide was tested and it should work, however there are many steps and they must be followed exactly as we describe, otherwise something might not work properly.

In all our guides and projects we always try to help if anyone gets stuck. However, in this particular case, there are so many steps that it can be extremely hard to help you without having access to the server and test it (of course, we don't have the resources to personally help everyone).

If you have any problem installing Mosquitto MQTT broker, preparing your Linux Ubuntu server, running Node-RED, installing an SSL certificate, contact Digital Ocean support and describe exactly what's happening. I've been using their service since 2015 and they always have an extremely helpful support team (or just use their Forum).

Now, if you want to install Mosquitto MQTT Broker on Digital Ocean, follow the next tutorial: [Run Your Cloud MQTT Mosquitto Broker \(access from anywhere using Digital Ocean\)](#).

Read the next guides to learn more about Node-RED:

- [Node-RED Dashboard – Getting Started](#)
- [ESP32 MQTT – Publish and Subscribe with Arduino IDE](#)
- [ESP32 MQTT – Publish BME280 Sensor Readings \(Arduino IDE\)](#)

**8 thoughts on “Access Node-RED Dashboard from Anywhere using Digital Ocean”**

**Otto Ziegler**

February 26, 2021 at 11:29 pm

I have tried following this tutorial, but have failed miserably. This is my time trying to set up anything on Ubuntu and I find it absolutely unworkable. Console window does not allow Highlighting, Copying or Pasting, so password had to be painstakingly copied by hand & then re-entered. Now when I try to open the Node Red terminal I get nothing.

Time to try something else – this is ridiculous.

If you do the Initial Server Setup with Ubuntu 20.04. tutorial you can use putty to connect to your server.

Hi,

I released a Node/App/Service called Remote-RED. With this you can access your Dashboard also from anywhere, but without having your Node-RED installed in the cloud. So also all other IoT/Smarthome connections are possible, that requires a local Node-RED.

Greetings!

Hi,

i have encountered a problem when I'm accessing the node-red software for the first time, it shows "Deceptive site ahead", is there any way to fix this ?

thank you

Installing globally on a current Ubuntu 20.04 puts it in /usr/bin so this is incorrect a fails.

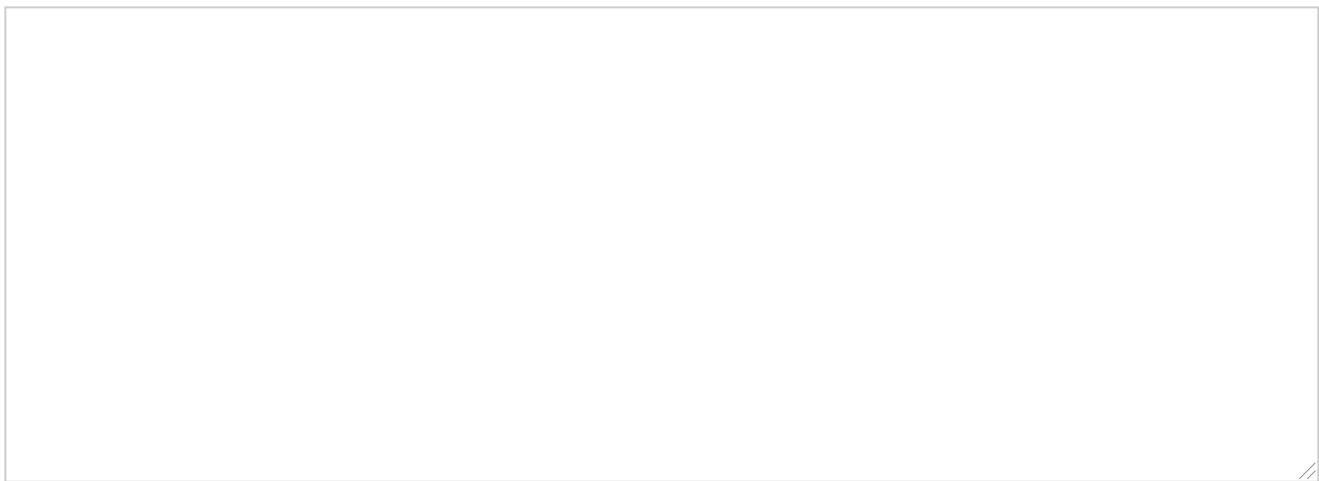

ExecStart=/usr/local/bin/node-red –max-old-space-size=128 -v

It's incorrect in the Digital Ocean instructions also....

Regards,
